Package: fiery (via r-universe)

October 5, 2024

Type Package

Title A Lightweight and Flexible Web Framework

Version 1.2.1.9000

Maintainer Thomas Lin Pedersen <thomasp85@gmail.com>

Description A very flexible framework for building server side logic
in R. The framework is unopinionated when it comes to how HTTP
requests and WebSocket messages are handled and supports all
levels of app complexity; from serving static content to
full-blown dynamic web-apps. Fiery does not hold your hand as
much as e.g. the shiny package does, but instead sets you free
to create your web app the way you want.

Fire   *Generate a New App Object*

Description

The Fire generator creates a new `Fire`-object, which is the class containing all the app logic. The class is based on the [R6](#) OO-system and is thus reference-based with methods and data attached to each object, in contrast to the more well known S3 and S4 systems. A `fiery` server is event driven, which means that it is build up and manipulated by adding event handlers and triggering events. To learn more about the `fiery` event model, read the [event vignette](#). `fiery` servers can be modified directly or by attaching plugins. As with events, [plugins has its own vignette](#).

Initialization:

A new 'Fire'-object is initialized using the `new()` method on the generator:

```
app <- Fire$new(host = '127.0.0.1', port = 8080L)
```

Copying:

As `Fire` objects are using reference semantics new copies of an app cannot be made simply be assigning it to a new variable. If a true copy of a `Fire` object is desired, use the `clone()` method.

Active bindings

host A string giving a valid IPv4 address owned by the server, or `'0.0.0.0'` to listen on all addresses. The default is `'127.0.0.1'`

port An integer giving the port number the server should listen on (defaults to `8080L`)

refresh_rate The interval in seconds between run cycles when running a blocking server (defaults to `0.001`)

refresh_rate_nb The interval in seconds between run cycles when running a non-blocking server (defaults to `1`)

trigger_dir A valid folder where trigger files can be put when running a blocking server (defaults to `NULL`). See the *[The event cycle in fiery](#)* vignette for more information.

plugins A named list of the already attached plugins. **Read Only** - can only be modified using the `attach()` method.

root The location of the app. Setting this will remove the root value from requests (or decline them with `400` if the request does not match the root). E.g. the path of a request will be changed from `/demo/test` to `/test` if `root == '/demo'`

access_log_format A [glue](#) string defining how requests will be logged. For standard formats see [common_log_format](#) and [combined_log_format](#). Defaults to the *Common Log Format*

Methods

Public methods:

- `Fire$new()`
- `Fire$format()`
- `Fire$ignite()`
- `Fire$start()`
- `Fire$reignite()`
- `Fire$resume()`
- `Fire$extinguish()`
- `Fire$stop()`
- `Fire$on()`
- `Fire$off()`
- `Fire$trigger()`
- `Fire$send()`
- `Fire$close_ws_con()`
- `Fire$attach()`
- `Fire$has_plugin()`
- `Fire$header()`
- `Fire$set_data()`
- `Fire$get_data()`
- `Fire$remove_data()`
- `Fire$time()`
- `Fire$remove_time()`
- `Fire$delay()`
- `Fire$remove_delay()`
- `Fire$async()`
- `Fire$remove_async()`
- `Fire$set_client_id_converter()`
- `Fire$set_logger()`
- `Fire$log()`
- `Fire$is_running()`
- `Fire$test_request()`
- `Fire$test_header()`
- `Fire$test_message()`
- `Fire$test_websocket()`
- `Fire$clone()`

Method new(): Create a new `Fire` app

Usage:

`Fire$new(host = "127.0.0.1", port = 8080)`

Arguments:

host A string overriding the default host

port An port number overriding the default port

Returns: A Fire object

Method format(): Human readable description of the app

Usage:
Fire$format(...)

Arguments:
... ignored

Returns: A character vector

Method ignite(): Begin running the server. Will trigger the start event

Usage:
Fire$ignite(block = TRUE, showcase = FALSE, ..., silent = FALSE)

Arguments:
block Should the console be blocked while running (alternative is to run in the background)
showcase Should the default browser open up at the server address
... Arguments passed on to the start handler
silent Should startup messaging by silenced

Method start(): Synonymous method to ignite()

Usage:
Fire$start(...)

Arguments:
... passed on to ignite()

Method reignite(): Resume a session. This is equivalent to ignite() but will also trigger the resume event

Usage:
Fire$reignite(...)

Arguments:
... passed on to ignite()

Method resume(): Synonymous method to reignite()

Usage:
Fire$resume(...)

Arguments:
... passed on to ignite()

Method extinguish(): Stop the server. Will trigger the end event

Usage:
Fire$extinguish()

Method stop(): Synonymous method to extinguish()

Usage:

`Fire$stop()`

Method `on()`: Add a handler to an event. See the *The event cycle in fiery* vignette for more information.

Usage:

`Fire$on(event, handler, pos = NULL)`

Arguments:

`event` The name of the event that should trigger the handler

`handler` The handler function that should be triggered

`pos` The position in the handler stack to place it at. `NULL` will place it at the end.

Returns: A unique string identifying the handler

Method `off()`: Remove an event handler from the app.

Usage:

`Fire$off(handlerId)`

Arguments:

`handlerId` The unique id identifying the handler

Method `trigger()`: Trigger an event in the app. This will cause any handler attached to the event to be called. See the *The event cycle in fiery* vignette for more information.

Usage:

`Fire$trigger(event, ...)`

Arguments:

`event` The name of the event

`...` Arguments passed on to the handlers

Returns: A named list containing the return values of all handlers attached to the event

Method `send()`: Send a Websocket message to a client. Will trigger the `send` event.

Usage:

`Fire$send(message, id)`

Arguments:

`message` The message to send

`id` The id of the client to send to. If missing, the message will be send to all clients

Method `close_ws_con()`: Close a Websocket connection. Will trigger the `websocket-closed` event

Usage:

`Fire$close_ws_con(id)`

Arguments:

`id` The id of the client to close the websocket connection to

Method `attach()`: Attach a plugin to the app. See the *[Creating and using fiery plugins](#)* vignette for more information

Usage:

`Fire$attach(plugin, ..., force = FALSE)`

Arguments:

`plugin` The plugin to attach

`...` Arguments to pass into the plugins `on_attach()` method

`force` If the plugin has already been attached an error is thrown, unless `force = TRUE` which tells the app to reattach it

Method `has_plugin()`: Check if the app has a plugin attached

Usage:

`Fire$has_plugin(name)`

Arguments:

`name` The name of the plugin

Returns: A boolean indicating if the given plugin is already attached

Method `header()`: Add a global http header that will be applied to all responses

Usage:

`Fire$header(name, value)`

Arguments:

`name` The name of the header

`value` The value of the header. Use `NULL` to remove the global header

Method `set_data()`: Add data to the global data store

Usage:

`Fire$set_data(name, value)`

Arguments:

`name` The name identifying the data

`value` The data to add

Method `get_data()`: Retrieve data from the global data store

Usage:

`Fire$get_data(name)`

Arguments:

`name` The name identifying the data

Returns: The data requested. Returns `NULL` if the store does not contain the requested data

Method `remove_data()`: Remove data from the global data store

Usage:

`Fire$remove_data(name)`

Arguments:

name The name identifying the data to be removed

Method `time()`: Add a timed evaluation that will be evaluated after the given number of seconds. See the *Delaying code execution in Fiery* vignette for more information

Usage:

`Fire$time(expr, then, after, loop = FALSE)`

Arguments:

expr The expression to evaluate when the time has passed

then A handler to call once expr has been evaluated

after The time in second to wait before evaluating expr

loop Should expr be called repeatedly with the interval given by after

Returns: A unique id identifying the handler

Method `remove_time()`: Remove a timed evaluation

Usage:

`Fire$remove_time(id)`

Arguments:

id The unique id identifying the handler

Method `delay()`: Add a delayed evaluation to be evaluated immediately at the end of the loop cycle. See the *Delaying code execution in Fiery* vignette for more information

Usage:

`Fire$delay(expr, then)`

Arguments:

expr The expression to evaluate at the end of the cycle

then A handler to call once expr has been evaluated

Returns: A unique id identifying the handler

Method `remove_delay()`: Remove a delayed evaluation

Usage:

`Fire$remove_delay(id)`

Arguments:

id The unique id identifying the handler

Method `async()`: Add an asynchronous evaluation to be evaluated in another process without blocking the server. See the *Delaying code execution in Fiery* vignette for more information

Usage:

`Fire$async(expr, then)`

Arguments:

expr The expression to evaluate at the end of the cycle

then A handler to call once expr has been evaluated

Returns: A unique id identifying the handler

Method `remove_async()`: Remove an async evaluation

Usage:

`Fire$remove_async(id)`

Arguments:

`id` The unique id identifying the handler

Method `set_client_id_converter()`: Sets the function that converts an HTTP request into a specific client id

Usage:

`Fire$set_client_id_converter(converter)`

Arguments:

`converter` A function with the argument `request`

Method `set_logger()`: Sets the logging function to use

Usage:

`Fire$set_logger(logger)`

Arguments:

`logger` A function with the arguments `event`, `message`, `request`, and `...`

Method `log()`: Log a message with the logger attached to the app. See [loggers](#) for build in functionality

Usage:

`Fire$log(event, message, request = NULL, ...)`

Arguments:

`event` The event associated with the message

`message` The message to log

`request` The `Request` object associated with the message, if any.

`...` Additional arguments passed on to the logger.

Method `is_running()`: Test if an app is running

Usage:

`Fire$is_running()`

Method `test_request()`: Send a request directly to the request logic of a non-running app. Only intended for testing the request logic

Usage:

`Fire$test_request(request)`

Arguments:

`request` The request to send

Method `test_header()`: Send a request directly to the header logic of a non-running app. Only intended for testing the request logic

Usage:

```
Fire$test_header(request)
```

Arguments:

request The request to send

Method `test_message()`: Send a message directly **to** the message logic of a non-running app. Only intended for testing the websocket logic

Usage:
```
Fire$test_message(request, binary, message, withClose = TRUE)
```

Arguments:

request The request to use to establish the connection

binary Is the message send in binary or character format

message The message to send. If `binary = FALSE` a character vector, if `binary = TRUE` a raw vector

withClose Should the websocket connection be closed at the end by the client

Method `test_websocket()`: Send a message directly **from** a non-running app. Only intended for testing the websocket logic

Usage:
```
Fire$test_websocket(request, message, close = TRUE)
```

Arguments:

request The request to use to establish the connection

message The message to send from the app

close Should the websocket connection be closed at the end by the server

Method `clone()`: The objects of this class are cloneable with this method.

Usage:
```
Fire$clone(deep = FALSE)
```

Arguments:

deep Whether to make a deep clone.

Examples

```
# Create a New App
app <- Fire$new(port = 4689)

# Setup the data every time it starts
app$on('start', function(server, ...) {
    server$set_data('visits', 0)
    server$set_data('cycles', 0)
})

# Count the number of cycles
app$on('cycle-start', function(server, ...) {
    server$set_data('cycles', server$get_data('cycles') + 1)
})
```

```
# Count the number of requests
app$on('before-request', function(server, ...) {
    server$set_data('visits', server$get_data('visits') + 1)
})

# Handle requests
app$on('request', function(server, ...) {
    list(
        status = 200L,
        headers = list('Content-Type' = 'text/html'),
        body = paste('This is indeed a test. You are number', server$get_data('visits'))
    )
})

# Show number of requests in the console
app$on('after-request', function(server, ...) {
    message(server$get_data('visits'))
    flush.console()
})

# Terminate the server after 300 cycles
app$on('cycle-end', function(server, ...) {
    if (server$get_data('cycles') > 300) {
        message('Ending...')
        flush.console()
        server$extinguish()
    }
})

# Be polite
app$on('end', function(server) {
    message('Goodbye')
    flush.console()
})

## Not run:
app$ignite(showcase = TRUE)

## End(Not run)
```

---

loggers	*App Logging*

Description

`fiery` has a build in logging mechanism that lets you capture event information however you like. Every user-injested warnings and errors are automatically captured by the logger along with most system errors as well. `fiery` tries very hard not to break due to faulty app logic. This means that any event handler error will be converted to an error log without `fiery` stopping. In the case of request handlers a 500L response will be send back if any error is encountered.

Usage

```
logger_null()

logger_console(format = "{time} - {event}: {message}")

logger_file(file, format = "{time} - {event}: {message}")

logger_switch(..., default = logger_null())

common_log_format

combined_log_format
```

Arguments

`format`	A [glue](#) string specifying the format of the log entry
`file`	A file or connection to write to
`...`	A named list of loggers to use for different events. The same semantics as [switch](#) is used so it is possible to let events *fall through* e.g. `logger_switch(error =, warning = logger_file('errors.log'))`.
`default`	A catch-all logger for use with events not defined in `...`

Format

An object of class `character` of length 1.

An object of class `character` of length 1.

Setting a logger

By default, `fiery` uses `logger_null()` which forwards warning and error messages to `stderr()` and ignores any other logging events. To change this behavior, set a different logger using the `set_logger()` method:

```
app$set_logger(logger)
```

where `logger` is a function taking at least the following arguments: `event`, `message`, `request`, `time`, and `...`.

`fiery` comes with some additional loggers, which either writes all logs to a file or to the console. A new instance of the file logger can be created with `logger_file(file)`:

```
app$set_logger(logger_file('fiery_log.log'))
```

A new instance of the console logger can be create with `logger_console()`:

```
app$set_logger(logger_console())
```

Both functions takes a `format` a argument that lets you customise how the log is written. Furthermore the console logger will style the logs with colour coding depending on the content if the console supports it.

As a last possibility it is possible to use different loggers dependent on the event by using the switch logger:

```
app$set_logger(logger_switch(warning =,
                             error = logger_file('errors.log),
                             default = logger_file('info.log')))
```

Automatic logs

`fiery` logs a number of different information by itself describing its operations during run. The following events are send to the log:

start Will be send when the server starts up

resume Will be send when the server is resumed

stop Will be send when the server stops

request Will be send when a request has been handled. The message will contain information about how long time it took to handle the request or if it was denied.

websocket Will be send every time a WebSocket connection is established or closed as well as when a message is received or send

message Will be send every time a message is emitted by an event handler or delayed execution handler

warning Will be send everytime a warning is emitted by an event handler or delayed execution handler

error Will be send everytime an error is signaled by an event handler or delayed execution handler. In addition some internal functions will also emit error event when exceptions are encountered

By default only *message*, *warning* and *error* events will be logged by sending them to the error stream as a `message()`.

Access Logs

Of particular interest are logs that detail requests made to the server. These are the `request` events detailed above. There are different standards for how requests are logged. `fiery` uses the *Common Log Format* by default, but this can be modified by setting the `access_log_format` field to a glue expression that has access to the following variables:

`start_time` The time the request was recieved

`end_time` The time the response was send back

`request` The Request object

`response` The Response object

`id` The client id

To change the format:

```
app$access_log_format <- combined_log_format
```

Custom logs

Apart from the standard logs described above it is also possible to send messages to the log as you please, e.g. inside event handlers. This is done through the `log()` method where you at the very least specify an event and a message. In general it is better to send messages through `log()` rather than with `warning()` and `stop()` even though the latters will eventually be caught, as it gives you more control over the logging and what should happen in the case of an exception.

An example of using `log()` in a handler could be:

```
app$on('header', function(server, id, request) {
  server$log('info', paste0('request from ', id, ' received'), request)
})
```

Which would log the timepoint the headers of a request has been recieved.
